## — Typeclasses

$(+)$  ::  $\text{Int} \rightarrow \text{Int} \rightarrow \text{Int}$  ? no...

$3 + 4$  ✓

$3.2 + 4.9$  ✓

$\text{True} + \text{False}$  ✗

$(+)$  ::  $a \rightarrow a \rightarrow a$  ? no...

$(==)$  ::  $\text{String} \rightarrow \text{String} \rightarrow \text{Bool}$  ? no...

$"\text{pikachu}" == "venusaur"$  ✓

$\text{True} == \text{True}$  ✓

$3 == 70$  ✓

$(\lambda x \rightarrow x) == (\lambda y \rightarrow y)$  ✗

$(==)$  ::  $a \rightarrow a \rightarrow \text{Bool}$  ? no...

Typeclasses address this issue.

"How to make ad hoc polymorphism less ad hoc"

↳ Wadler + Blott, 1989

Typeclasses — Haskell (since the 90s)

Traits — Rust

Interfaces — Java

Concepts — C++

Think of a typeclass as a set of operations that you can do on values of any type that implements that typeclass.

examples:

- for types that implement Num, you can do +, -, \*, abs, etc.
- for types that implement Eq, you can do ==, /=.
- for types that implement Show, you can do show.
