Today: type inference and polymorphism

$$\frac{n \in \mathbb{Z}}{\Gamma \vdash n :: \text{Int}} \quad [\text{T-Num}]$$

$$\frac{\Gamma \vdash e_1 :: \text{Int} \quad \Gamma \vdash e_2 :: \text{Int}}{\Gamma \vdash e_1 + e_2 :: \text{Int}} \quad [\text{T-Add}]$$

$$\frac{\text{if } (x, T) \text{ is in } \Gamma}{\Gamma \vdash x :: T} \quad [\text{T-Var}]$$

$$\frac{\Gamma, (x, T_1) \vdash e :: T_2}{\Gamma \vdash \lambda x \rightarrow e :: T_1 \rightarrow T_2} \quad [\text{T-Lam}]$$

$$\frac{\Gamma \vdash e_1 :: T_1 \rightarrow T_2 \quad \Gamma \vdash e_2 :: T_1}{\Gamma \vdash e_1 e_2 :: T_2} \quad [\text{T-App}]$$

$$\frac{\Gamma \vdash e_1 :: T_1 \quad \Gamma, (x, T_1) \vdash e_2 :: T_2}{\Gamma \vdash \text{let } \underbrace{x = e_1}_{\text{in}} e_2 :: \boxed{T_2}} \quad [\text{T-Let}]$$

$$\boxed{\Gamma \vdash e :: T}$$

we've defined this relation.

An expression is well-typed in  $\Gamma$  if we can derive  $\Gamma \vdash e :: T$  for some type  $T$ .

If we can't do that, the expression is ill-typed.

In general, the idea here is to figure out the types of expressions without evaluating any expressions — rather, just by using the typing rules.

example:  $\text{let } x=1 \text{ in } x+2$

$$\begin{array}{c}
 \frac{}{1 \in \mathbb{Z}} \quad [T\text{-Num}] \quad \frac{(x, \text{Int}) \text{ is in } [(x, \text{Int})] [T\text{-Var}] \quad 2 \in \mathbb{Z}}{[(x, \text{Int})] \vdash 2 :: \text{Int}} [T\text{-Add}] \\
 \frac{[(x, \text{Int})] \vdash x :: \text{Int} \quad [(x, \text{Int})] \vdash 2 :: \text{Int}}{[(x, \text{Int})] \vdash x+2 :: \text{Int}} [T\text{-Add}] \\
 \frac{[ ] \vdash 1 :: \text{Int} \quad [(x, \text{Int})] \vdash x+2 :: \text{Int}}{[ ] \vdash \text{let } x=1 \text{ in } x+2 :: \text{Int}} [T\text{-Let}]
 \end{array}$$

example:  $(\lambda x \rightarrow x) 2$

$$\begin{array}{c}
 \frac{(x, \text{Int}) \text{ is in } [(x, \text{Int})]}{[(x, \text{Int})] \vdash x :: \text{Int}} [T\text{-Var}] \\
 \frac{[(x, \text{Int})] \vdash x :: \text{Int}}{[ ] \vdash \lambda x \rightarrow x :: \text{Int} \rightarrow \text{Int}} [T\text{-Lam}] \quad \frac{2 \in \mathbb{Z}}{[ ] \vdash 2 :: \text{Int}} [T\text{-Num}] \\
 \frac{[ ] \vdash \lambda x \rightarrow x :: \text{Int} \rightarrow \text{Int} \quad [ ] \vdash 2 :: \text{Int}}{[ ] \vdash (\lambda x \rightarrow x) 2 :: \text{Int}} [T\text{-App}]
 \end{array}$$

example:  $(\lambda x \rightarrow x x)$  is ill-typed.

$$\begin{array}{c}
 \frac{(x, T_1) \text{ is in } [(x, T_1)]}{[(x, T_1)] \vdash x :: T_1} [T\text{-Var}] \quad \frac{(x, T_1) \text{ is in } [(x, T_1)]}{[(x, T_1)] \vdash x :: T_1} [T\text{-Var}] \\
 \frac{[(x, T_1)] \vdash x :: T_1 \quad [(x, T_1)] \vdash x :: T_1}{[(x, T_1)] \vdash x x :: \text{"}} [T\text{-App}] \\
 \frac{[(x, T_1)] \vdash x x :: \text{"}}{[ ] \vdash (\lambda x \rightarrow x x) :: \text{"}} [T\text{-Lam}]
 \end{array}$$

What about  $\lambda x \rightarrow x$ ? What's its type?

We could use the rules to derive

- \*  $\text{Int} \rightarrow \text{Int}$ ,
- \*  $(\text{Int} \rightarrow \text{Int}) \rightarrow (\text{Int} \rightarrow \text{Int})$ ,
- or  $T \rightarrow T$  for any  $T$ .

What we really want, though, is to derive a single, most general type for every expression.

let  $f = \lambda x \rightarrow x$  in  
let  $x = \underline{f}$  5 in  
 $\underline{f}$  ( $\lambda z \rightarrow z + y$ )

What should the type here be?

$\text{Int} \rightarrow \text{Int} \dots$

but the typing rules (so far) say this is ill-typed!

$\lambda z \rightarrow z + 5$

The problem here is that our typing rules forced us to pick only one type for  $f$ , even though different uses of it call for different types.

$\lambda x \rightarrow x :: \text{forall } a. a \rightarrow a$

This is the real type of  $\lambda x \rightarrow x$ , also known as a type scheme or just a polytype.

We can instantiate a type scheme into different types, by replacing the bound type variable (in this case,  $a$ ) with some type.

instantiating  $\text{forall } a. a \rightarrow a$  with  $\text{Int}$  gives us  $\text{Int} \rightarrow \text{Int}$ .

instantiating  $\text{forall } a. a \rightarrow a$  with  $\text{Int} \rightarrow \text{Int}$  gives us  $(\text{Int} \rightarrow \text{Int}) \rightarrow (\text{Int} \rightarrow \text{Int})$

We need to tweak our rules to allow this.

At a high level, type inference works as follows. (for this example)

1) when we have to pick a type  $T$  for a variable  $x$ , we pick a fresh type variable  $a$ .

2) so, the type of  $\lambda x \rightarrow x$  comes out as  $a \rightarrow a$

3) we generalize this to  $\text{forall } a. a \rightarrow a$   $F = \lambda x \rightarrow x$

4) when we apply  $f$ , we instantiate it with  $\text{Int}$  or  $\text{Int} \rightarrow \text{Int}$  as needed for each application.

Let's make this happen:

$T ::= \text{Int} \mid T_1 \rightarrow T_2 \mid a$

↑ type variables.

We now also have type schemes, aka polytypes

$S ::= T \mid \text{forall } a. S$

$[(z, \text{Int}), (f, \text{forall } a. a \rightarrow a)]$

↑ Type environments can now contain polytypes.

we now need a notion of type substitutions.

A type substitution maps type variables to types.

example:  $[("a", \text{Int}), ("b", c \rightarrow c)]$

Applying a type substitution to a type  $T$  means replacing all the type variables in  $T$  with whatever the type substitution binds them to.

$[("a", \text{Int}), ("b", c \rightarrow c)] (a \rightarrow a)$   
would give me:  $\text{Int} \rightarrow \text{Int}$

$[("a", \text{Int}), ("b", c \rightarrow c)] (b \rightarrow c)$   
would give me:  $(c \rightarrow c) \rightarrow c$

and so on.

We'll change the T-Var rule and the T-Let rule to talk about type schemes.

$(x, S)$  is in  $\Gamma$   
 $\frac{}{\Gamma \vdash x :: S}$  [T-Var]

$\frac{\Gamma \vdash e_1 :: S \quad \Gamma, (x, S) \vdash e_2 :: T}{\Gamma \vdash \text{let } x = e_1 \text{ in } e_2 :: T}$  [T-Let]

Two new rules that let us

- generalize a type into a type scheme
- instantiate a type scheme into a type

$\frac{\Gamma \vdash e :: S}{\Gamma \vdash e :: \text{forall } a. S}$  [T-Inst]

$\Gamma \vdash e :: S$  but with the type substitution  $[("a", T)]$  applied for some  $T$ .

e.g.  $\text{forall } a. a \rightarrow a$   
could become  $\text{Int} \rightarrow \text{Int}$ .

$\frac{\Gamma \vdash e :: S}{\Gamma \vdash e :: \text{forall } a. S}$  [T-Gen]

where  $a$  is a fresh type variable not occurring in  $\Gamma$ .

Let's do an example:

what's the type of  $\lambda x \rightarrow x$ ?  
(we want it to be  $\text{forall } a. a \rightarrow a$ )

$(x, a)$  is in  $[(x, a)]$   
 $\frac{}{[(x, a)] \vdash x :: a}$  [T-Var]

$\frac{}{[] \vdash \lambda x \rightarrow x :: a \rightarrow a}$  [T-Lam]

$\frac{}{[] \vdash \lambda x \rightarrow x :: \text{forall } a. a \rightarrow a}$  [T-Gen]

let  $f = \lambda x \rightarrow x$  in  
 let  $y = f\ 5$  in  
 $f\ (\lambda z \rightarrow z + y)$

should have type:  
 $Int \rightarrow Int$   
 Let's try to derive this.

(easy use of T-Lam and T-Add)

$[(f, forall \dots), (y, Int)] \vdash \lambda z \rightarrow z + y :: Int \rightarrow Int$

[T-App]

$[(f, forall \dots), (y, Int)] \vdash f(\lambda z \rightarrow z + y) :: Int \rightarrow Int$

$(f, forall \dots)$  is in  $[(f, forall \dots), (y, Int)]$  [T-Var]

$[(f, forall \dots), (y, Int)] \vdash f :: forall a. a \rightarrow a$  [T-Inst]

$[(f, forall \dots), (y, Int)] \vdash f :: (Int \rightarrow Int) \rightarrow (Int \rightarrow Int)$

$(f, forall \dots)$  is in  $[(f, forall \dots)]$  [T-Var]

$[(f, forall \dots)] \vdash f :: forall a \dots [T-Inst]$

$[(f, forall \dots)] \vdash f :: Int \rightarrow Int$  [T-App]

$[(f, forall a. a \rightarrow a)] \vdash f\ 5 :: Int$

[T-Num]

[T-Let]

$[(f, forall a. a \rightarrow a)] \vdash \text{let } y = f\ 5 \text{ in } \dots :: Int \rightarrow Int$

(previous example)

$[\ ] \vdash \lambda x \rightarrow x :: forall a. a \rightarrow a$

$[\ ] \vdash \text{let } f = \lambda x \rightarrow x \text{ in } \dots :: Int \rightarrow Int$  [T-Let]

Key idea of the previous typing derivation:  
We used the [T-Inst] rule twice. Once we used it to instantiate  $\text{forall } a. a \rightarrow a$  with  $\text{Int}$ , resulting in  $\text{Int} \rightarrow \text{Int}$ . And once we used it to instantiate  $\text{forall } a. a \rightarrow a$  with  $\text{Int} \rightarrow \text{Int}$ , resulting in  $(\text{Int} \rightarrow \text{Int}) \rightarrow (\text{Int} \rightarrow \text{Int})$ .

The binding  $(f, \text{forall } a. a \rightarrow a)$  was in our type environment, and every time we used  $f$  from the type environment (with the [T-Var] rule), we used [T-Inst] to instantiate it as needed!
