

CSE114A Lecture 10

agenda:

- Type classes!

$(+) :: \text{Num } a \Rightarrow a \rightarrow a \rightarrow a$

$3 + 4 \quad \checkmark$

$3.4 + 5.7 \quad \checkmark$

$"pikachu" + "venusaur" \quad \times$

$\text{True} + \text{True} \quad \times$

$(\lambda x \rightarrow x) + (\lambda x \rightarrow x) \quad \times$

Int, Double, etc. all implement the Num type class.

One way to think of a type class:

A set of operations that you can do on values of of any type that implements that type class.

- For types that implement Num (e.g., Int, Double, etc.), you can do (+), (-), (*), (abs), etc.

- For types that implement Eq, you can do (==) (/=).

Another example:

$(==) :: \text{Eq } a \Rightarrow a \rightarrow a \rightarrow \text{Bool}$

$5 == 6 \quad \checkmark$

$"pikachu" == "venusaur" \quad \checkmark$

$\text{True} == \text{True} \quad \checkmark$

$(\lambda x \rightarrow x) == (\lambda x \rightarrow y) \quad \times$

"How to make ad hoc polymorphism less ad hoc"

- Wadler and Blott, 1988

↑ Introduced the idea of typeclasses

- Haskell - type classes (since the 90s)
- Rust - traits (since 2012)
- Java - interfaces (since ~2010-2015)
- C++ - concepts ?
