# Your favorite language

---

- Probably has lots of features:
  - **Assignment** ( $x = x + 1$ )
  - **Booleans, integers, characters, strings,...**
  - **Conditionals**
  - **Loops, return, break, continue**
  - **Functions**
  - **Recursion**
  - **References / pointers**
  - **Objects and classes**
  - **Inheritance**
  - ... and more

# The Lambda Calculus

---

- Features
  - **?**Functions
  - (that's it)

# The Lambda Calculus

---

- Seriously...

- ~~Assignment (`x = x + 1`)~~
- ~~Booleans, integers, characters, strings, ...~~
- ~~Conditionals~~
- ~~Loops, `return`, `break`, `continue`~~
- **Functions**
- ~~Recursion~~
- ~~References / pointers~~
- ~~Objects and classes~~
- ~~Inheritance~~
- ~~... and more~~

The only thing you can do is:  
**Define a function**  
**Call a function**

# Describing a Programming Language

---

- **Syntax**
  - What do programs *look like?*
- **Semantics**
  - What do programs *mean?*
  - **Operational semantics:**
    - How do programs *execute step-by-step?*

# Syntax: What programs look like

---

```
e ::= x  
    | \x -> e  
    | e1 e2
```

- A set of *expressions*  $e$  (aka *programs* or  $\lambda$ -*terms*)
- There are three kinds of expressions
  - **Variables:** eg  $x, y, z$
  - **Function definitions** (aka abstractions)  $\lambda x \rightarrow e$ 
    - $x$  is the *formal parameter*,  $e$  is the *body*
  - **Function calls** (aka application)  $e1 e2$ 
    - $e1$  is the *function*,  $e2$  is the *argument*

# Examples

---

-- *The identity function ("for any x compute x")*

$\lambda x \rightarrow x$

-- *A function that returns the identity function*

$\lambda x \rightarrow (\lambda y \rightarrow y)$

-- *A function that applies its argument to*

-- *the identity function*

$\lambda f \rightarrow f (\lambda x \rightarrow x)$

# QUIZ: Lambda syntax

---

Which of the following terms are syntactically incorrect? \*

- A.  $\lambda(\lambda x \rightarrow x) \rightarrow y$
- B.  $\lambda x \rightarrow x x$
- C.  $\lambda x \rightarrow x (y x)$
- D. A and C
- E. All of the above

<http://tiny.cc/cse116-lambda-ind>

# QUIZ: Lambda syntax

---

Which of the following terms are syntactically incorrect? \*

- A.  $\lambda(\lambda x \rightarrow x) \rightarrow y$
- B.  $\lambda x \rightarrow x x$
- C.  $\lambda x \rightarrow x (y x)$
- D. A and C
- E. All of the above

<http://tiny.cc/cse116-lambda-grp>

# Semantics: Scope of a Variable

---

- The part of a program where a **variable is visible**
- In the expression  $\lambda x \rightarrow e$ 
  - $x$  is the newly introduced variable
  - $e$  is the scope of  $x$
  - any occurrence of  $x$  in  $\lambda x \rightarrow e$  is bound (by the binder  $\lambda x$ )

# Semantics: Scope of a Variable

---

- For example,  $x$  is **bound** in:

$\lambda x \rightarrow x$

$\lambda x \rightarrow (\lambda y \rightarrow x)$

- An occurrence of  $x$  in  $e$  is **free** if it's *not bound* by an enclosing abstraction
- For example,  $x$  is **free** in:

$x y$  -- *no binders at all!*

$\lambda y \rightarrow x y$  -- *no  $\lambda x$  binder*

$(\lambda x \rightarrow \lambda y \rightarrow y) x$  --  *$x$  is outside the scope  
of the  $\lambda x$  binder;*  
-- *intuition: it's not "the same"  $x$*

# QUIZ: Variable scope

---

In the expression  $(\lambda x \rightarrow x) x$ , is x bound or free? \*

- A. bound
- B. free
- C. first occurrence is bound, second is free
- D. first occurrence is bound, second and third are free
- E. first two occurrences are bound, third is free

<http://tiny.cc/cse116-scope-ind>

# QUIZ: Variable scope

---

In the expression  $(\lambda x \rightarrow x) x$ , is x bound or free? \*

- A. bound
- B. free
- C. first occurrence is bound, second is free
- D. first occurrence is bound, second and third are free
- E. first two occurrences are bound, third is free

<http://tiny.cc/cse116-scope-grp>

# Free Variables

---

- A variable  $x$  is **free** in  $e$  if there exists a free occurrence of  $x$  in  $e$
- We can formally define the set of all free variables in a term like so:

$$\text{FV}(x) = ???$$

$$\text{FV}(\lambda x \rightarrow e) = ???$$

$$\text{FV}(e_1 e_2) = ???$$

# Free Variables

---

- A variable  $x$  is **free** in  $e$  if there exists a free occurrence of  $x$  in  $e$
- We can formally define the set of all free variables in a term like so:

$$\text{FV}(x) = \{x\}$$

$$\text{FV}(\lambda x \rightarrow e) = \text{FV}(e) - \{x\}$$

$$\text{FV}(e_1 e_2) = \text{FV}(e_1) \cup \text{FV}(e_2)$$

# Closed Expressions

---

- If  $e$  has no free variables it is said to be closed
- Closed expressions are also called **combinators**
  - Q: What is the *shortest* closed expression?

# Closed Expressions

---

- If  $e$  has no free variables it is said to be closed
- Closed expressions are also called **combinators**
  - Q: What is the *shortest* closed expression?
  - A:  $\lambda x \rightarrow x$

# Semantics: What programs mean

---

- How do I “run” or “execute” a  $\lambda$ -term?
- Think of middle-school algebra:
  - *Simplify expression:*
  - $(x + 2)*(3*x - 1)$
  - =
  - ???
- **Execute** = rewrite step-by-step following simple rules until no more rules apply

# Rewrite rules of lambda calculus

---

1.  $\alpha$ -step (aka renaming formals)
2.  $\beta$ -step (aka function call)

# Semantics: $\beta$ -Reduction

---

$$(\lambda x \rightarrow e1) \ e2 =_{\beta} e1[x := e2]$$

where  $e1[x := e2]$  means “ $e1$  with all free occurrences of  $x$  replaced with  $e2$ ”

- Computation by *search-and-replace*:
  - If you see an *abstraction* applied to an argument, take the *body* of the abstraction and replace all free occurrences of the *formal* by that argument
  - We say that  $(\lambda x \rightarrow e1) \ e2$   $\beta$ -steps to  $e1[x := e2]$

# Examples

---

```
(\x -> x) apple  
=b> apple
```

Is this right? Ask Elsa!

```
(\f -> f (\x -> x)) (give apple)  
=b> ???
```

# Examples

---

```
(\x -> x) apple  
=b> apple
```

Is this right? Ask Elsa!

```
(\f -> f (\x -> x)) (give apple)  
=b> give apple (\x -> x)
```

# QUIZ: $\beta$ -Reduction 1

---

$(\lambda x \rightarrow (\lambda y \rightarrow y)) \text{apple} =_{\beta} ??? *$

- A. apple
- B.  $\lambda y \rightarrow \text{apple}$
- C.  $\lambda x \rightarrow \text{apple}$
- D.  $\lambda y \rightarrow y$
- E.  $\lambda x \rightarrow y$

<http://tiny.cc/cse116-beta1-ind>

# QUIZ: $\beta$ -Reduction 1

---

$(\lambda x \rightarrow (\lambda y \rightarrow y)) \text{ apple} =_{\beta} ???$

- A. apple
- B.  $\lambda y \rightarrow \text{apple}$
- C.  $\lambda x \rightarrow \text{apple}$
- D.  $\lambda y \rightarrow y$
- E.  $\lambda x \rightarrow y$

<http://tiny.cc/cse116-beta1-grp>

# QUIZ: $\beta$ -Reduction 2

---

$(\lambda x \rightarrow x (\lambda x \rightarrow x)) \text{ apple} =_{\beta} ??? *$

- A.  $\text{apple} (\lambda x \rightarrow x)$
- B.  $\text{apple} (\lambda \text{apple} \rightarrow \text{apple})$
- C.  $\text{apple} (\lambda x \rightarrow \text{apple})$
- D.  $\text{apple}$
- E.  $\lambda x \rightarrow x$

<http://tiny.cc/cse116-beta2-ind>

# QUIZ: $\beta$ -Reduction 2

---

$(\lambda x \rightarrow x (\lambda x \rightarrow x)) \text{ apple} =_{\beta} ??? *$

- A.  $\text{apple} (\lambda x \rightarrow x)$
- B.  $\text{apple} (\lambda \text{apple} \rightarrow \text{apple})$
- C.  $\text{apple} (\lambda x \rightarrow \text{apple})$
- D.  $\text{apple}$
- E.  $\lambda x \rightarrow x$

<http://tiny.cc/cse116-beta2-grp>

# A Tricky One

---

$$\begin{aligned} & (\lambda x \rightarrow (\lambda y \rightarrow x))\ y \\ =& b> (\lambda y \rightarrow y) \end{aligned}$$

Is this right?

**Problem:** the free  $y$  in the argument has been *captured* by  $\lambda y$ !

**Solution:** make sure that all *free variables* of the argument are different from the *binders* in the body.

# Capture-Avoiding Substitution

---

- We have to fix our definition of  $\beta$ -reduction:

$$(\lambda x \rightarrow e_1) \ e_2 =_{\beta} e_1[x := e_2]$$

where  $e_1[x := e_2]$  means “ ~~$e_1$  with all free occurrences of  $x$  replaced with  $e_2$~~ ”

- $e_1$  with all *free* occurrences of  $x$  replaced with  $e_2$ , **as long as** no free variables of  $e_2$  get captured
- undefined otherwise

# Capture-Avoiding Substitution

---

Formally:

$$x[x := e] = e$$

$$y[x := e] = y \quad \text{-- assuming } x \neq y$$

$$(e1\ e2)[x := e] = (e1[x := e])\ (e2[x := e])$$

$$(\lambda x \rightarrow e1)[x := e] = \lambda x \rightarrow e1 \quad \text{-- why just `e1`?}$$

$$(\lambda y \rightarrow e1)[x := e]$$

$$\mid \text{not } (y \text{ in } FV(e)) = \lambda y \rightarrow e1[x := e]$$

$$\mid \text{otherwise} = \text{undefined} \quad \text{-- but what then??}$$

# Semantics: $\alpha$ -Reduction

---

# Semantics: $\alpha$ -Reduction

---

$$\lambda x \rightarrow e =_{\alpha} \lambda y \rightarrow e[x := y]$$

**where  $y$  not in  $FV(e)$**

- We can rename a formal parameter and replace all its occurrences in the body
- We say that  $(\lambda x \rightarrow e)$   *$\alpha$ -steps* to  $(\lambda y \rightarrow e[x := y])$

# Semantics: $\alpha$ -Reduction

---

$$\begin{array}{ll} \backslash x \rightarrow e & =a> \quad \backslash y \rightarrow e[x := y] \\ & \text{where } y \text{ not in } FV(e) \end{array}$$

- Example:

$$\begin{array}{ll} \backslash x \rightarrow x & \\ =a> \quad \backslash y \rightarrow y & \\ =a> \quad \backslash z \rightarrow z & \end{array}$$

- All these expressions are  $\alpha$ -equivalent

# Example

---

What's wrong with these?

-- (A)

$\lambda f \rightarrow f\ x =a> \lambda x \rightarrow x\ x$

-- (B)

$(\lambda x \rightarrow \lambda y \rightarrow y)\ y =a> (\lambda x \rightarrow \lambda z \rightarrow z)\ z$

-- (C)

$\lambda x \rightarrow \lambda y \rightarrow x\ y =a> \lambda \text{apple} \rightarrow \lambda \text{orange} \rightarrow \text{apple}\ \text{orange}$

# The Tricky One

---

```
(\x -> (\y -> x)) y  
=a> ???
```

To avoid getting confused, you can always rename formals, so that different variables have different names!

# The Tricky One

---

```
(\x -> (\y -> x)) y  
=a> (\x -> (\z -> x)) y  
=b> \z -> y
```

To avoid getting confused, you can always rename formals, so that different variables have different names!

# Normal Forms

---

A **redex** is a  $\lambda$ -term of the form

$$(\lambda x \rightarrow e_1) e_2$$

A  $\lambda$ -term is in **normal form** if it contains no redexes.

# QUIZ: Normal form

---

Which of the following terms are not in normal form ? \*

- A.  $x$
- B.  $x y$
- C.  $(\lambda x \rightarrow x) y$
- D.  $x (\lambda y \rightarrow y)$
- E. C and D

<http://tiny.cc/cse116-norm-ind>

# QUIZ: Normal form

---

Which of the following terms are not in normal form ? \*

- A.  $x$
- B.  $x y$
- C.  $(\lambda x \rightarrow x) y$
- D.  $x (\lambda y \rightarrow y)$
- E. C and D

<http://tiny.cc/cse116-norm-grp>

# Semantics: Evaluation

---

- A  $\lambda$ -term  $e$  evaluates to  $e'$  if

1. There is a sequence of steps

$$e \rightarrow e_1 \rightarrow \dots \rightarrow e_N \rightarrow e'$$

where each  $\rightarrow$  is either  $=a>$  or  $=b>$

2.  $e'$  is in *normal form*

# Example of evaluation

---

$(\lambda x \rightarrow x) \text{ apple}$   
=?> apple

$(\lambda f \rightarrow f (\lambda x \rightarrow x)) (\lambda x \rightarrow x)$   
=?> ???

$(\lambda x \rightarrow x x) (\lambda x \rightarrow x)$   
=?> ???

# Example of evaluation

---

$(\lambda x \rightarrow x) \text{ apple}$   
=?> apple

$(\lambda f \rightarrow f (\lambda x \rightarrow x)) (\lambda x \rightarrow x)$   
=?>  $(\lambda x \rightarrow x) (\lambda x \rightarrow x)$   
=?>  $\lambda x \rightarrow x$

$(\lambda x \rightarrow x x) (\lambda x \rightarrow x)$   
=?> ???

# Example of evaluation

---

$(\lambda x \rightarrow x) \text{ apple}$   
=b>  $\text{apple}$

$(\lambda f \rightarrow f (\lambda x \rightarrow x)) (\lambda x \rightarrow x)$   
=b>  $(\lambda x \rightarrow x) (\lambda x \rightarrow x)$   
=b>  $\lambda x \rightarrow x$

$(\lambda x \rightarrow x x) (\lambda x \rightarrow x)$   
=b>  $(\lambda x \rightarrow x) (\lambda x \rightarrow x)$   
=b>  $\lambda x \rightarrow x$

# Elsa shortcuts

---

- Named  $\lambda$ -terms

```
let ID = \x -> x -- abbreviation for \x -> x
```

- To substitute a name with its definition, use a =d> step:

```
ID apple  
=d> (\x -> x) apple -- expand definition  
=b> apple           -- beta-reduce
```

# Elsa shortcuts

---

- Evaluation
  - $e1 =^*> e2$ :  $e1$  reduces to  $e2$  in 0 or more steps
    - where each step is  $=a>$ ,  $=b>$ , or  $=d>$
  - $e1 =\sim> e2$ :  $e1$  evaluates to  $e2$
- *What is the difference?*

# Non-Terminating Evaluation

---

$(\lambda x \rightarrow x\ x) (\lambda x \rightarrow x\ x)$

=b> ???

# Non-Terminating Evaluation

---

$(\lambda x \rightarrow x\ x) (\lambda x \rightarrow x\ x)$

=b>  $(\lambda x \rightarrow x\ x) (\lambda x \rightarrow x\ x)$

- Oh no... we can write programs that loop back to themselves
- And never reduce to normal form!
- This combinator is called  $\Omega$

# Non-Terminating Evaluation

---

- What if we pass  $\Omega$  as an argument to another function?

```
let OMEGA = (\x -> x x) (\x -> x x)
```

```
(\x -> \y -> y) OMEGA
```

- Does this reduce to a normal form? Try it at home!

# Programming in $\lambda$ -calculus

---

- Real languages have lots of features
  - Multi-argument functions
  - Booleans
  - Records (structs, tuples)
  - Numbers
  - Recursion
- Let's see how to encode all of these features with the  $\lambda$ -calculus.

# Multi-Argument Functions

---

-- *The identity function ("for any x compute x")*

`\x -> x`

-- *A function that returns the identity function*

`\x -> (\y -> y)`

-- *A function that applies its argument to*

-- *the identity function*

`\f -> f (\x -> x)`

- How do I define a function with two arguments?
  - e.g. a function that takes x and y and returns y

# Multi-Argument Functions

---

-- A function that returns the identity function

```
\x -> (\y -> y)
```

OR: a function that takes two arguments  
and returns the second one!

- How do I define a function with two arguments?
  - e.g. a function that takes x and y and returns y

# Multi-Argument Functions

---

- How do I apply a function to two arguments?
  - e.g. apply  $\lambda x \rightarrow (\lambda y \rightarrow y)$  to apple and banana?  
-- *first apply to apple, then apply the result to banana*

$((((\lambda x \rightarrow (\lambda y \rightarrow y)) \text{ apple}) \text{ banana})$

# Syntactic Sugar

---

- Convenient notation used as a shorthand for valid syntax

instead of	we write
$\lambda x \rightarrow (\lambda y \rightarrow (\lambda z \rightarrow e))$	$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$
$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$	$\lambda x y z \rightarrow e$
$((e_1 e_2) e_3) e_4$	$e_1 e_2 e_3 e_4$

$\lambda x y \rightarrow y$  -- A function that takes two arguments  
-- and returns the second one...

$(\lambda x y \rightarrow y)$  apple banana -- ... applied to two arguments

# Programming in $\lambda$ -calculus

---

- Real languages have lots of features
  - Multi-argument functions
  - Booleans
  - Records (structs, tuples)
  - Numbers
  - Recursion

# $\lambda$ -calculus: Booleans

---

- How can we encode Boolean values (TRUE and FALSE) as functions?
- Well, what do we do with a Boolean  $b$ ?
  - We make a *binary choice*

`if b then e1 else e2`

# Booleans: API

---

- We need to define three functions

```
let TRUE  = ???
```

```
let FALSE = ???
```

```
let ITE   = \b x y -> ??? -- if b then x else y
```

*such that*

```
ITE TRUE apple banana =~> apple
```

```
ITE FALSE apple banana =~> banana
```

(Here, **let NAME = e** means NAME is an *abbreviation* for e)

# Booleans: Implementation

---

```
let TRUE  = \x y -> x          -- Returns first argument
let FALSE = \x y -> y          -- Returns second argument
let ITE   = \b x y -> b x y    -- Applies cond. to branches
                                -- (redundant, but
                                -- improves readability)
```

# Example: Branches step-by-step

---

```
eval ite_true:  
ITE TRUE e1 e2  
=d> (\b x y -> b      x  y) TRUE e1 e2  -- expand def ITE  
=b>   (\x y -> TRUE x  y)          e1 e2  -- beta-step  
=b>     (\y -> TRUE e1 y)          e2  -- beta-step  
=b>           TRUE e1 e2          -- expand def TRUE  
=d>     (\x y -> x) e1 e2          -- beta-step  
=b>       (\y -> e1)   e2          -- beta-step  
=b> e1
```

# Example: Branches step-by-step

---

- Now you try it!
- Can you fill in the blanks to make it happen?
  - <http://goto.ucsd.edu/elsa>

```
eval ite_false:
```

```
ITE FALSE e1 e2
```

-- *fill the steps in!*

```
=b> e2
```

# Example: Branches step-by-step

---

```
eval ite_false:
```

```
ITE FALSE e1 e2
```

```
=d> (\b x y -> b      x  y) FALSE e1 e2 -- expand def ITE
```

```
=b>   (\x y -> FALSE x  y)           e1 e2 -- beta-step
```

```
=b>     (\y -> FALSE e1 y)           e2 -- beta-step
```

```
=b>           FALSE e1 e2           -- expand def TRUE
```

```
=d>     (\x y -> y) e1 e2           -- beta-step
```

```
=b>     (\y -> y)   e2           -- beta-step
```

```
=b> e2
```

# Boolean operators

---

- Now that we have ITE it's easy to define other Boolean operators:

```
let NOT = \b      -> ???
```

```
let AND = \b1 b2 -> ???
```

```
let OR  = \b1 b2 -> ???
```

# Boolean operators

---

- Now that we have ITE it's easy to define other Boolean operators:

```
let NOT = \b      -> ITE b FALSE TRUE
```

```
let AND = \b1 b2 -> ITE b1 b2 FALSE
```

```
let OR   = \b1 b2 -> ITE b1 TRUE b2
```

# Boolean operators

---

- Now that we have ITE it's easy to define other Boolean operators:

**let NOT = \b**       $\rightarrow$  **b FALSE TRUE**

**let AND = \b1 b2**  $\rightarrow$  **b1 b2 FALSE**

**let OR = \b1 b2**  $\rightarrow$  **b1 TRUE b2**

- (since ITE is redundant)
- *Which definition to do you prefer and why?*

# Programming in $\lambda$ -calculus

---

- Real languages have lots of features
  - **Booleans** [done]
  - **Records (structs, tuples)**
  - **Numbers**
  - **Functions** [we got those]
  - **Recursion**

# $\lambda$ -calculus: Records

---

- Let's start with records with two fields (aka pairs)?
- Well, what do we **do** with a pair?
  1. Pack two items into a pair, then
  2. Get first item, or
  3. Get second item.

# Pairs: API

---

- We need to define three functions

```
let PAIR = \x y -> ???      -- Make a pair with x and y
                                -- { fst : x, snd : y }
let FST  = \p -> ???      -- Return first element
                                -- p.fst
let SND  = \p -> ???      -- Return second element
                                -- p.snd
```

*such that*

```
FST (PAIR apple banana) =~> apple
SND (PAIR apple banana) =~> banana
```

# Pairs: Implementation

---

- A pair of  $x$  and  $y$  is just something that lets you pick between  $x$  and  $y$ ! (I.e. a function that takes a boolean and returns either  $x$  or  $y$ )

```
let PAIR = \x y -> (\b -> ITE b x y)
let FST  = \p -> p TRUE    -- call w/ TRUE, get 1st value
let SND  = \p -> p FALSE   -- call w/ FALSE, get 2nd value
```

# Exercise: Triples?

---

- How can we implement a record that contains **three** values?

```
let TRIPLE = \x y z -> ???
```

```
let FST3  = \t -> ???
```

```
let SND3  = \t -> ???
```

```
let TRD3  = \t -> ???
```

# Exercise: Triples?

---

- How can we implement a record that contains **three** values?

```
let TRIPLE = \x y z -> PAIR x (PAIR y z)  
let FST3   = \t -> FST t  
let SND3   = \t -> FST (SND t)  
let TRD3   = \t -> SND (SND t)
```

# Programming in $\lambda$ -calculus

---

- Real languages have lots of features
  - Multi-argument functions
  - Booleans
  - Records (structs, tuples)
  - Numbers
  - Recursion

# $\lambda$ -calculus: Numbers

---

- Let's start with **natural numbers** (0, 1, 2, ...)
- What do we do with natural numbers?
  1. **Count:** 0, inc
  2. **Arithmetic:** dec, +, -, \*
  3. **Comparisons:** ==, <=, etc

# Natural Numbers: API

---

- We need to define:
  - A family of **numerals**: **ZERO**, **ONE**, **TWO**, **THREE**, ...
  - Arithmetic functions: **INC**, **DEC**, **ADD**, **SUB**, **MULT**
  - Comparisons: **IS\_ZERO**, **EQ**

Such that they respect all regular laws of arithmetic, e.g.

**IS\_ZERO ZERO**       $\leadsto$  **TRUE**

**IS\_ZERO (INC ZERO)**  $\leadsto$  **FALSE**

**INC ONE**       $\leadsto$  **TWO**

...

# Pairs: Implementation

---

- Church numerals: a *number N* is encoded as a combinator that *calls a function on an argument N times*

```
let ONE    = \f x -> f x
let TWO    = \f x -> f (f x)
let THREE  = \f x -> f (f (f x))
let FOUR   = \f x -> f (f (f (f x)))
let FIVE   = \f x -> f (f (f (f (f x))))
let SIX   = \f x -> f (f (f (f (f (f x))))))
```

...

# QUIZ: Church Numerals

---

Which of these is a valid encoding of ZERO ? \*

- A: let ZERO =  $\lambda f x \rightarrow x$
- B: let ZERO =  $\lambda f x \rightarrow f$
- C: let ZERO =  $\lambda f x \rightarrow f x$
- D: let ZERO =  $\lambda x \rightarrow x$
- E: None of the above

<http://tiny.cc/cse116-church-ind>

# QUIZ: Church Numerals

---

Which of these is a valid encoding of ZERO ? \*

- A: let ZERO =  $\lambda f x \rightarrow x$
- B: let ZERO =  $\lambda f x \rightarrow f$
- C: let ZERO =  $\lambda f x \rightarrow f x$
- D: let ZERO =  $\lambda x \rightarrow x$
- E: None of the above

<http://tiny.cc/cse116-church-grp>

# $\lambda$ -calculus: Increment

---

```
-- Call `f` on `x` one more time than `n` does
let INC = \n -> (\f x -> ???)
```

- Example

```
eval inc_zero :
  INC ZERO
  => (\n f x -> f (n f x)) ZERO
  => \f x -> f (ZERO f x)
  => \f x -> f x
  => ONE
```

# QUIZ: ADD

---

How shall we implement ADD? \*

- A. let ADD = \n m -> n INC m
- B. let ADD = \n m -> INC n m
- C. let ADD = \n m -> n m INC
- D. let ADD = \n m -> n (m INC)
- E. let ADD = \n m -> n (INC m)

<http://tiny.cc/cse116-add-ind>

# QUIZ: ADD

---

How shall we implement ADD? \*

- A. let ADD = \n m -> n INC m
- B. let ADD = \n m -> INC n m
- C. let ADD = \n m -> n m INC
- D. let ADD = \n m -> n (m INC)
- E. let ADD = \n m -> n (INC m)

<http://tiny.cc/cse116-add-grp>

# $\lambda$ -calculus: Addition

---

-- Call `f` on `x` exactly `n + m` times

```
let ADD = \n m -> n INC m
```

- Example

```
eval add_one_zero :
```

```
ADD ONE ZERO
```

```
=~> ONE
```

# QUIZ: MULT

---

How shall we implement MULT? \*

- A. let MULT = \n m -> n ADD m
- B. let MULT = \n m -> n (ADD m) ZERO
- C. let MULT = \n m -> m (ADD n) ZERO
- D. let MULT = \n m -> n (ADD m ZERO)
- E. let MULT = \n m -> (n ADD m) ZERO

<http://tiny.cc/cse116-mult-ind>

# QUIZ: MULT

---

How shall we implement MULT? \*

- A. let MULT = \n m -> n ADD m
- B. let MULT = \n m -> n (ADD m) ZERO
- C. let MULT = \n m -> m (ADD n) ZERO
- D. let MULT = \n m -> n (ADD m ZERO)
- E. let MULT = \n m -> (n ADD m) ZERO

<http://tiny.cc/cse116-mult-grp>

# $\lambda$ -calculus: Multiplication

---

-- Call `f` on `x` exactly `n \* m` times

```
let MULT = \n m -> n (ADD m) ZERO
```

- Example

```
eval two_times_one :
```

```
  MULT TWO ONE
```

```
=~> TWO
```

# Programming in $\lambda$ -calculus

---

- Real languages have lots of features
  - Multi-argument functions
  - Booleans
  - Records (structs, tuples)
  - Numbers
  - Recursion

# $\lambda$ -calculus: Recursion

---

- I want to write a function that sums up natural numbers up to n:

$\lambda n \rightarrow \dots$       --  $1 + 2 + \dots + n$

# QUIZ: SUM

---

Is this a correct implementation of SUM? \*

```
let SUM = \n -> ITE (ISZ n)
    ZERO
    (ADD n (SUM (DEC n)))
```

- A. Yes
- B. No

<http://tiny.cc/cse116-sum-ind>

# QUIZ: SUM

---

Is this a correct implementation of SUM? \*

```
let SUM = \n -> ITE (ISZ n)
    ZERO
    (ADD n (SUM (DEC n)))
```

- A. Yes
- B. No

<http://tiny.cc/cse116-sum-grp>

# $\lambda$ -calculus: Recursion

---

- No! Named terms in Elsa are just syntactic sugar
- To translate an Elsa term to  $\lambda$ -calculus: replace each name with its definition

```
\n -> ITE (ISZ n)
      ZERO
      (ADD n (SUM (DEC n))) -- But SUM is
                                -- not a thing!
```

- **Recursion:** Inside this function I want to call the same function on DEC n
- Looks like we can't do recursion, because it requires being able to refer to functions *by name*, but in  $\lambda$ -calculus functions are *anonymous*.
- *Right?*

# $\lambda$ -calculus: Recursion

---

- Think again!
- Recursion: ~~Inside this function I want to call the same function on DEC n~~
  - Inside this function I want to call a function on DEC n
  - And BTW, I want it to be the same function
- Step 1: Pass in the function to call “recursively”

```
let STEP =
  \rec ->
    \n -> ITE (ISZ n)
          ZERO
          (ADD n (rec (DEC n))) -- Call some rec
```

# $\lambda$ -calculus: Recursion

---

- Step 1: Pass in the function to call “recursively”

```
let STEP =
  \rec ->
    \n -> ITE (ISZ n)
          ZERO
          (ADD n (rec (DEC n))) -- Call some rec
```

- Step 2: Do something clever to **STEP**, so that the function passed as `rec` itself becomes

```
\n -> ITE (ISZ n) ZERO (ADD n (rec (DEC n)))
```

# $\lambda$ -calculus: Fixpoint Combinator

---

- Wanted: a combinator **FIX** such that **FIX STEP** calls **STEP** with itself as the first argument:

```
FIX STEP  
=*> STEP (FIX STEP)
```

(In math: a *fixpoint* of a function  $f(x)$  is a point  $x$ , such that  $f(x) = x$ )

- Once we have it, we can define:

```
let SUM = FIX STEP
```

- Then by property of **FIX** we have:

```
SUM =*> STEP SUM -- (1)
```

# $\lambda$ -calculus: Fixpoint Combinator

```
eval sum_one:  
  SUM ONE  
=*> STEP SUM ONE          -- (1)  
=d> (\rec n -> ITE (ISZ n) ZERO (ADD n (rec (DEC n)))) SUM ONE  
=b>      (\n -> ITE (ISZ n) ZERO (ADD n (SUM (DEC n)))) ONE  
                  -- ^^^ the magic happened!  
=b>          ITE (ISZ ONE) ZERO (ADD ONE (SUM (DEC ONE)))  
=*> ADD ONE (SUM ZERO)      -- def of ISZ, ITE, DEC, ...  
=*> ADD ONE (STEP SUM ZERO) -- (1)  
=d> ADD ONE  
    ((\rec n -> ITE (ISZ n) ZERO (ADD n (rec (DEC n)))) SUM ZERO)  
=b> ADD ONE ((\n -> ITE (ISZ n) ZERO (ADD n (SUM (DEC n)))) ZERO)  
=b> ADD ONE (ITE (ISZ ZERO) ZERO (ADD ZERO (SUM (DEC ZERO))))  
=b> ADD ONE ZERO  
=~> ONE
```

# $\lambda$ -calculus: Fixpoint Combinator

---

- So how do we define **FIX**?
- Remember  $\Omega$ ? It *replicates itself!*

$$\begin{aligned} & (\lambda x \rightarrow x x) (\lambda x \rightarrow x x) \\ = b > & (\lambda x \rightarrow x x) (\lambda x \rightarrow x x) \end{aligned}$$

- We need something similar but more involved.

# $\lambda$ -calculus: Fixpoint Combinator

---

- The Y combinator discovered by Haskell Curry:

```
let FIX = \stp -> (\x -> stp (x x)) (\x -> stp (x x))
```

- How does it work?

```
eval fix_step:
```

```
    FIX STEP
```

```
=d> (\stp -> (\x -> stp (x x)) (\x -> stp (x x))) STEP
=b>           (\x -> STEP (x x)) (\x -> STEP (x x))
=b> STEP     ((\x -> STEP (x x)) (\x -> STEP (x x)))
--          ^^^^^^ this is FIX STEP ^^^^^^
```
